

Same grid, same method (getStability()), cod vs anchovy

hopf = spectral_radius ≥ 1 with a complex dominant eigenvalue

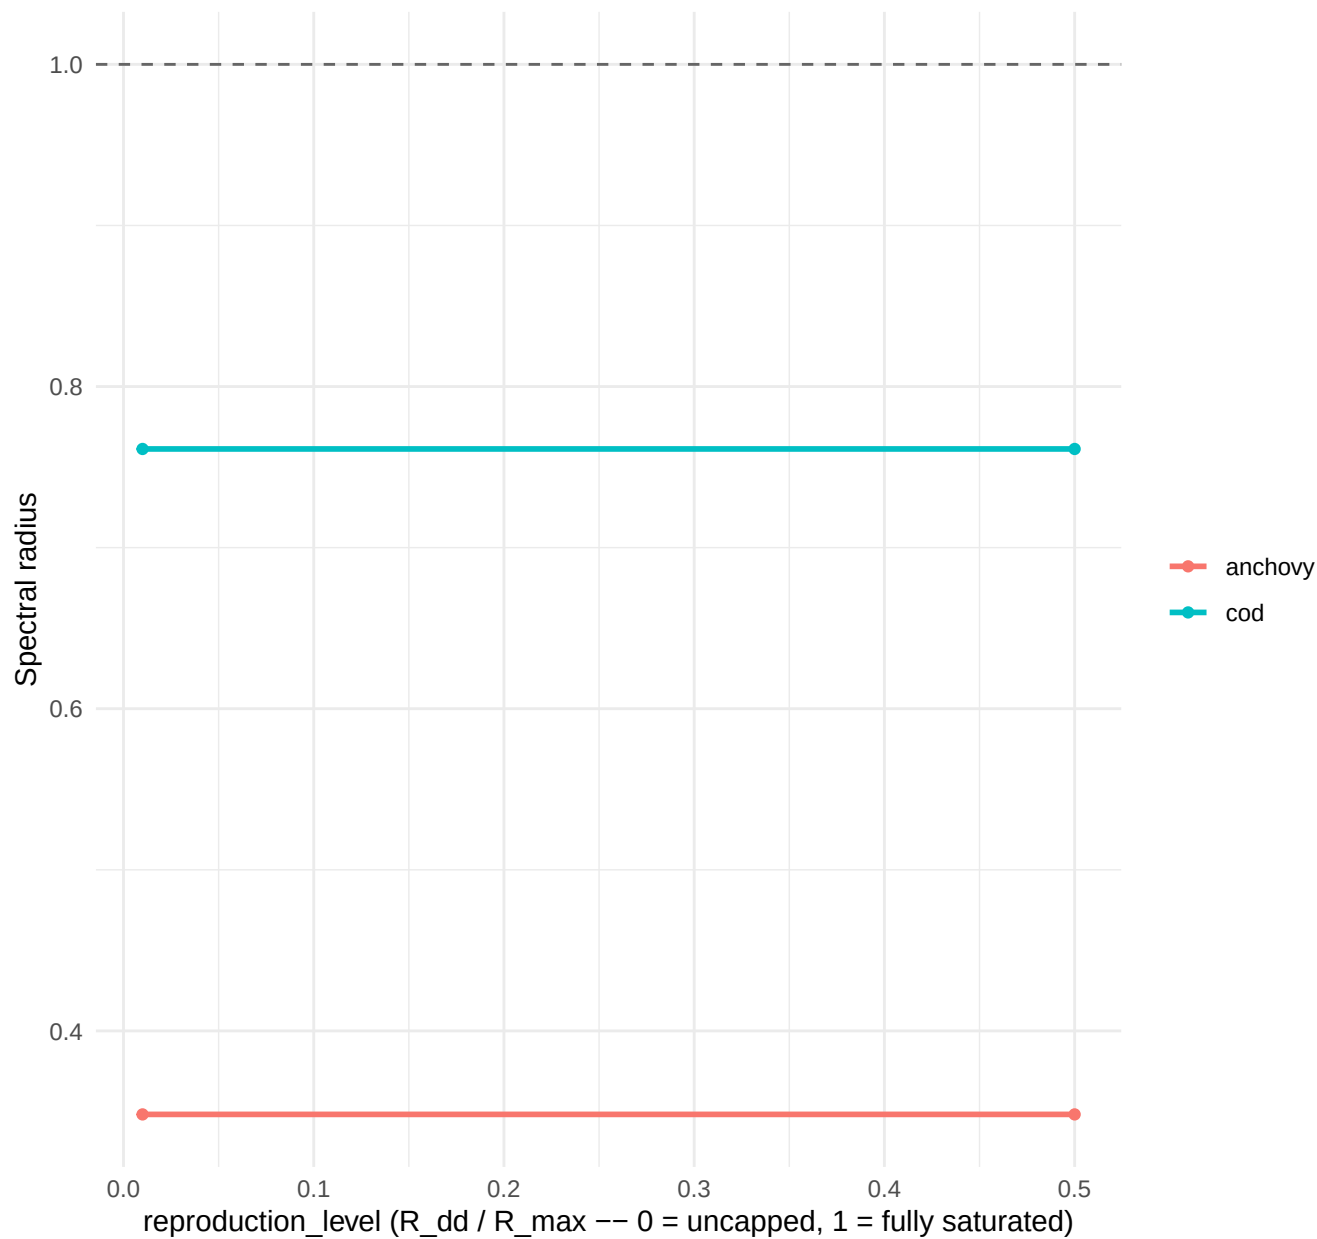

Isolating the lever: body size x intake-rate parameters

Anchovy template throughout; 'cod' body/rates swap in cod_params' own w_max/w_mat or gam

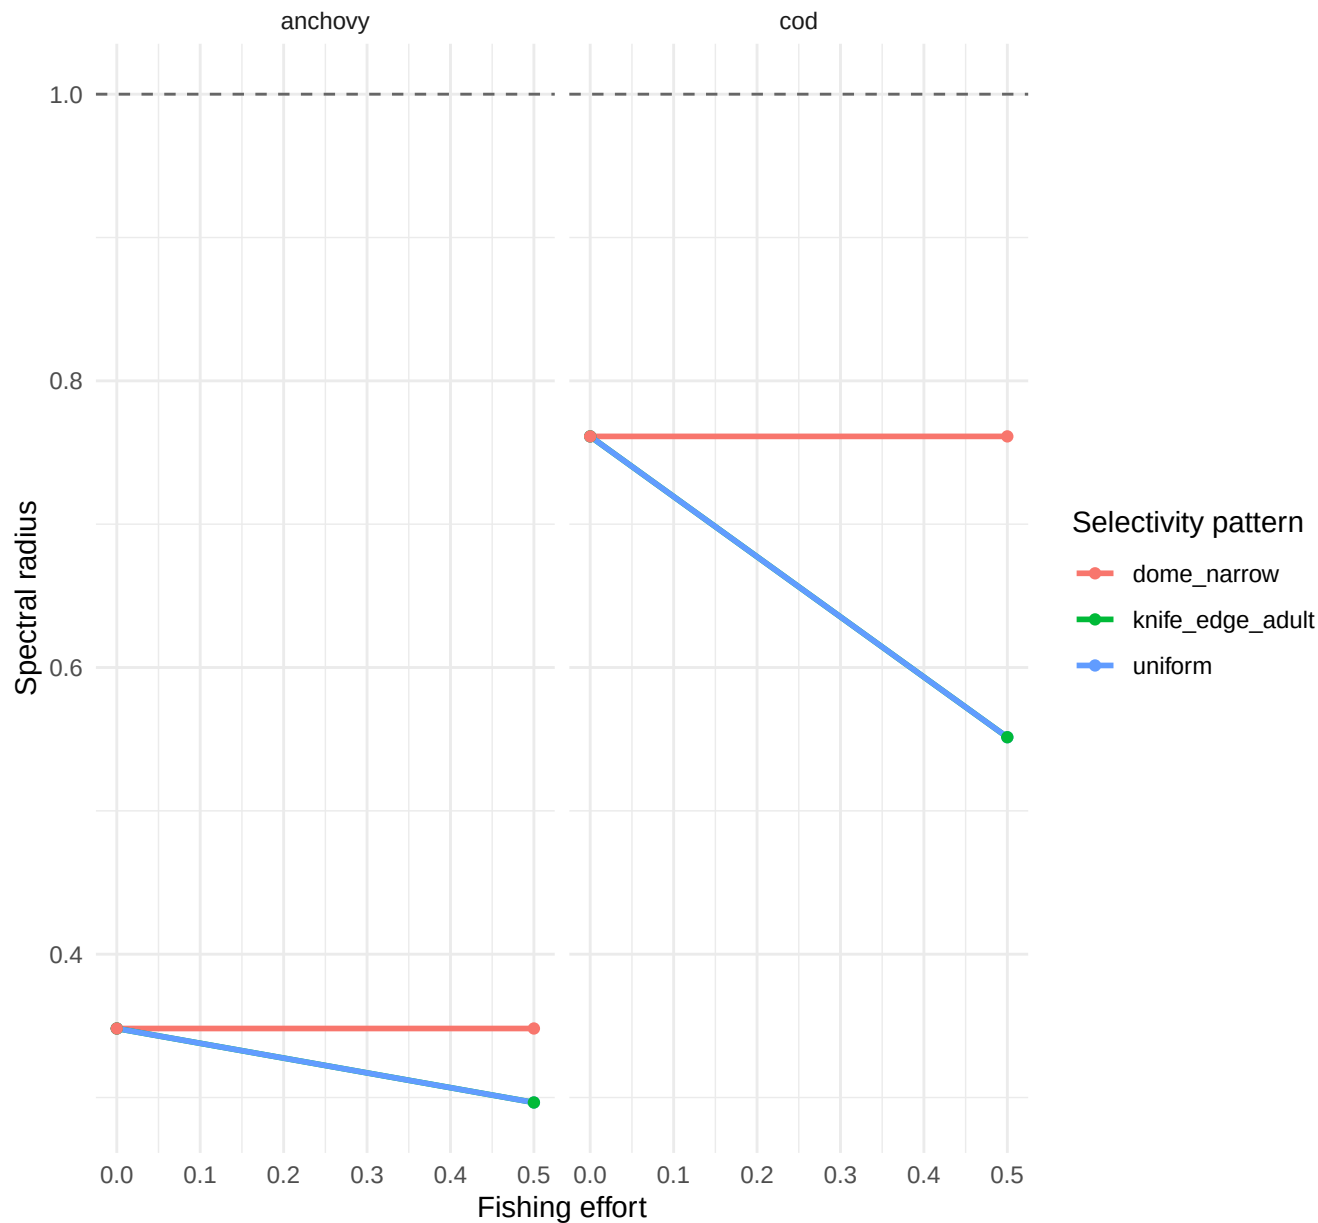

Does adding Beverton–Holt recruitment compensation ever destabilise?

Reference point (resource_decrease=0.001, capacity_mult=10); dashed = stability boundary

Does narrow size-selective fishing destabilise where uniform fishing doesn't?

Andersen & Pedersen (2010): narrow-band selectivity is the most destabilising fishing pattern

Does pushing capacity_mult well past Section 2's 20x cap ever destabilise?
resource_decrease fixed at 0.001 (the reference point)
